The pelican eel (Eurypharynx pelecanoides) is a deep-sea eel rarely seen by humans, though it is occasionally caught in fishing nets. It is the only known member of the genus Eurypharynx and the family Eurypharyngidae.

Pelican eel - Wikipedia

Leptocephalus is the flat and transparent larva of the eel, marine eels, and other members of the superorder Elopomorpha. This is one of the most diverse groups of teleosts, containing 801 species in 4 orders, 24 families, and 156 genera. This group is thought to have arisen in the Cretaceous period over 140 million years ago. Fishes with a leptocephalus larval stage include the most familiar eels such as the conger, moray eel, and garden eel as well as members of the family Anguillidae, plus mo

Leptocephalus - Wikipedia

Leptocephalus is a genus that was used for species of larval eels, called leptocephali, that were thought to be new fish species, or whose adult eel species were not known. Leptocephali differ so much in appearance from their adults that the larvae and adults of eels are not easily matched, and when first discovered, leptocephali were thought to be a distinct type of fishes, [1] but not eels.

Leptocephalus (genus) - Wikipedia

Leptocephali of American and European eels <5 mm long are distributed between 50 and 300 m deep both day and night, perhaps indicative of the spawning depth of eels. Larger leptocephali perform daily vertical migrations, which increase in magnitude with increasing body size. Those 5-20 mm long descend from 50-100 m deep by night to 100-150 m deep by day.

These fishes were widely scattered in teleost classifications until Greenwood et al. (1966) united them in the superorder Elopomorpha based on the fact that representatives of all subgroups have a leptocephalus larva. 1 Some authors have disputed that the leptocephalus is a derived feature of elopomorphs, preferring instead to regard it as the generalized teleost larval condition (Harrison, 1966; Nybelin, 1971; Hulet and Robins, 1989).

Eloipforms, along with other elopomorphs, have a ribbonlike, translucent, pelagic larva (leptocephalus) that undergoes a striking metamorphosis involving shrinkage to about half the maximum larval size. The newly hatched leptocephali may be carried out to sea by offshore currents, but metamorphosis only occurs close inshore, and it is probable that larvae carried far out to sea die.
